Abstract

We deal with three availability systems with warm standby components, fault detection delay and general repair times. Failure times and repair times of failed components are exponentially and generally distributed, respectively. Detection delay times are also exponentially distributed. A recursive method is used to develop steady-state availability, \((Av)\), for three systems. We present extensive numerical computations to compare three systems for the \((Av)\) based on specific values given to the system parameters.

Keywords: Availability, comparative analysis, detection delay, supplementary variable, warm standby components.

1. Introduction

We study three availability systems with warm standby components, detection delay and general repair times. A recursive method is used to develop steady-state availability, \((Av)\), for three systems. The concept of detection delay for a repairable system was introduced by Trivedi\textsuperscript{(1)}. Wang and Pearn\textsuperscript{(2)} studied the cost benefit analysis of series systems with warm standby units and imperfect coverage was investigated by Wang and Chiu\textsuperscript{(3)}. Further, they explored a comparative analysis which provided numerical results to show the effects of various values of system parameters to the cost/benefit ratios. Recently, Wang and Chen\textsuperscript{(4)} considered the availability characteristics between three different systems with reboot delay, switching failures, and general repair times. The reliability characteristics of a repairable system with balk and reneging was examined by Ke and Wang\textsuperscript{(5)}. A repairable system with imperfect coverage and reboot was analyzed by Ke and Liu\textsuperscript{(6)}. They derived the steady-state probabilities of down units at an arbitrary epoch. Singh et al.\textsuperscript{(7)} developed the transitional state probabilities, asymptotic behavior and some system characteristics such as reliability, availability, mean time to system failure, and the cost effectiveness of the system using the supplementary variable technique.

Ke et al.\textsuperscript{(8)} considered a repairable system with detection, imperfect coverage and reboot by means of the Bayesian approach. An application of stochastic Petri nets to compute the availability of safety critical on demand systems was proposed by Kleyner and Volovoi\textsuperscript{(9)}. Cekyay, and Ozekici\textsuperscript{(10)} derived system reliability, mean time to failure, and steady-state availability on coherent systems and series connection of \(k\)-out-of-\(n\) standby subsystems with exponentially distributed component lifetimes. A constructive method to optimize the availability of a system through modeling the dependency of the components was proposed by Yu et al.\textsuperscript{(11)}.

2. System description

For the sake of discussion, we consider a data center requires a 30MW power electricity, and assume that the electricity generation capacity of components is available in units of 30MW, 15MW, and 10MW. To provide reliable and stable power supply, there are standby components, and all primary and standby components are continuously monitored by a fault detecting device to identify if they fail. The standby components are always required for the failure situation. Primary and standby components are assumed to be repairable. The primary and warm standby components fail independently and their times to failure are
exponentially distributed with parameters \( \lambda \) and \( \alpha \) \((0 < \alpha < 1)\), respectively. When one of primary components fails, an available warm standby with failure rate \( \alpha \) is converted into a primary component with failure rate \( \lambda \). Whenever one of these components fails, it immediately detect other component. We assume that the detection delay has an exponential distribution with parameter \( \delta \). During the time the fault is being detected, and the last primary component fail, the system is assumed to fail. Such a fault is called a near-coincident fault. The system fails when the standby components are emptied for which we defined as the state of system failure (sf). It is assumed that the time-to-repair of the components are independent and identically distributed (i.i.d.) random variables having a distribution \( B(u) \) \((u \geq 0)\), a probability density function \( b(u) \) \((u \geq 0)\) and mean repair time \( b_1 \). If the remaining electricity generation capacity is less than 30MW, the system will stop working. When the failed component arrives at the repair facility, if the server is available, the component will be repaired. If a primary component (or a standby component) fails, it is immediately repaired based on the first-come, first-served (FCFS) discipline. We assume that the server can repair only one failed component at a time, and that the service is independent of the failure of components. Once a component is repaired, it is as good as new.

We consider the following three availability systems: the first system consists of one 30 MW primary component and one 30 MW warm standby component. The second system is composed of two 15 MW primary components and one 15 MW warm standby component. The third system includes three 10 MW primary components and two 10 MW warm standby components.

### 2.1 Availability system 1

Availability system 1 consists of one 30 MW primary component and one 30 MW warm standby component. The state-transition-rate diagram of availability system 1 is shown in Fig. 1, where the state labeled \((1,1)\) denotes the detection stage. The transition from state \((1,1)\) to state \((1,0)\) (at rate \( \delta \)) indicates the detection of the fault.

![State transition diagram](image)

Fig. 1. The state-transition-rate diagram of availability system 1.

The state labeled \(sf\) denotes the system failure. We define

\[
P_{1i}(u) = b(u)P_{1i}.
\]

then we obtain the following steady-state equations

\[
0 = -(\lambda + \alpha)P_{2,0} + P_{1,0}(0),
\]

\[
0 = -(\lambda + \delta)P_{1,1} + (\lambda + \alpha)P_{2,0},
\]

\[
\frac{d}{du} P_{1,0}(u) = -\lambda P_{1,0}(u) + \delta b(u)P_{1,1} + b(u)P_0(0),
\]

\[
\frac{d}{du} P_{1,1}(u) = \lambda P_{1,1}(u) + \lambda b(u)P_{1,1}.
\]

We assume that the detection state \((1,1)\) is a system down state. For availability system 1, the explicit expression for the steady-state availability, \(Av_{1}\), is given by

\[
Av_1 = P_{2,0} + P_{1,0} = \frac{(\lambda + \delta)\left[\lambda + \alpha - \alpha B(\lambda)\right]}{\lambda \Delta_1}
\]

### Special cases

We develop the following explicit expressions for the \(Av_{1w}, Av_{1e}, Av_{1d}\) for three different repair time distributions such as exponential, \(k\)-stage Erlang, and deterministic, respectively.

**Case 1. Exponential repair time**

The explicit expression for the \(Av_{1w}\) is given by

\[
Av_{1w} = \frac{(\lambda + \delta)\left[\lambda + \alpha - \alpha \mu \right]}{\lambda (\mu + \lambda) \Delta_1}
\]

**Case 2. \(k\)-stage Erlang repair time**

The explicit expression for the \(Av_{1e}\)

\[
Av_{1e} = \frac{(\lambda + \delta)\left[(\lambda + \alpha)(k \mu + \lambda) - \alpha (k \mu)^\dagger\right]}{\lambda k \Delta_1}
\]

**Case 3. Deterministic repair time**

The explicit expression for the \(Av_{1d}\) is given by

\[
Av_{1d} = \frac{(\lambda + \delta)(\lambda + \alpha - \alpha \epsilon / \lambda)}{\lambda \Delta_1}
\]

### 2.2 Availability system 2

Availability system 2 consists of two 15 MW primary
components and one 15 MW warm standby component. The state-transition-rate diagram of availability system 2 is presented in Fig. 2, where the state labeled (2,1) represents the detection stage.

![Fig. 2. The state-transition-rate diagram of availability system 2.](image)

We get the following steady-state equations:

\[ 0 = -(2\lambda + \alpha)P_{s,0} + P_{s,0}(0), \quad (7) \]
\[ 0 = -(2\lambda + \delta)P_{s,1} + (2\lambda + \alpha)P_{s,0}, \quad (8) \]
\[ -\frac{d}{du} P_{s,0}(u) = -2\lambda P_{s,0}(u) + \delta b(u)P_{s,2} + b(u)P_{s,0}(0), \quad (9) \]
\[ -\frac{d}{du} P_{s,1}(u) = 2\lambda P_{s,1}(u) + 2\lambda b(u)P_{s,2} \quad (10) \]

For availability system 2, the explicit expression for the steady-state availability, \( Av_{s} \), is given by

\[ Av_{s} = P_{s,0} + P_{s,1} = \frac{(2\lambda + \delta)[2\lambda + \alpha - \alpha B^{'}(2\lambda)]}{2\lambda \Delta_{s}}, \quad (11) \]

**Special cases**

For availability system 2, we get

\[ Av_{s,m} = \frac{(2\lambda + \delta)[(2\lambda + \alpha)(\mu + 2\lambda) - \alpha \mu]}{2\lambda \mu + 2\lambda \Delta_{s}} \]
\[ Av_{s,s} = \frac{(2\lambda + \delta)[(2\lambda + \alpha)(k\mu + 2\lambda) - \alpha (k\mu)^{s}]}{2\lambda (k\mu + 2\lambda) \Delta_{s}} \]
\[ Av_{s,d} = \frac{(2\lambda + \delta)(2\lambda + \alpha - \alpha e^{-\alpha/\mu})}{2\lambda \Delta_{s}}. \]

### 2.3 Availability system 3

Availability system 3 includes three 10 MW primary components and two 10 MW warm standby components. The state-transition-rate diagram of availability system 3 is shown in Fig. 3, the states labeled (4,1), (3,2) and (3,1) represent the detection stages.

![Fig. 3. The state-transition-rate diagram of availability system 3.](image)

Using the same procedure, then we get the steady-state equations. For availability system 3, the explicit expression for the steady-state availability, \( Av_{s} \), is given by

\[ Av_{s} = \left\{ 1 + \frac{(3\lambda + 2\alpha)[1 - B^{'}(3\lambda + \alpha)]}{(3\lambda + \alpha)B^{'}(3\lambda + \alpha)} \right. \]
\[ + \frac{(3\lambda + 2\alpha)[3\lambda + \alpha + \delta - \delta B^{'}(3\lambda + \alpha)]}{3\lambda B^{'}(3\lambda)} \left[ 1 - B^{'}(3\lambda) \right] \]
\[ \frac{P_{s,0}}{P_{s,0}}. \]

**Special cases**

For availability system 3, we obtain the following expressions for the \( Av_{s,m}, Av_{s,s}, Av_{s,d} \):

\[ Av_{s,m} = \left\{ (3\lambda + 2\alpha)[(3\lambda + \alpha + \delta)(\mu + 3\lambda + \alpha) - \delta \mu] \right. \]
\[ + (3\lambda + 2\alpha + \mu)(3\lambda + \alpha + \delta) \left\} \right. \]
\[ \frac{P_{s,0}}{P_{s,0}}. \]

\[ Av_{s,s} = 1 + \frac{(3\lambda + 2\alpha)[(k\mu + 3\lambda + \alpha)^{s} - (k\mu)^{s}]}{(3\lambda + \alpha)(k\mu)^{s}} \]
\[ + \frac{\Phi_{1}[(k\mu + 3\lambda)^{s} - (k\mu)^{s}]}{3\lambda(k\mu)^{s}} P_{s,0}, \]

\[ Av_{s,d} = 1 + \frac{(3\lambda + 2\alpha) e^{3\lambda/\mu} - 1}{3\lambda + \alpha} \]
\[ + \frac{(3\lambda + 2\alpha)[(3\lambda + \alpha + \delta)e^{3\lambda/\mu} - \delta]}{3\lambda + \alpha + \delta} \left[ e^{3\lambda/\mu} - 1 \right] P_{s,0}, \]

where

\[ \Phi_{1} = \frac{(3\lambda + 2\alpha)[(3\lambda + \alpha + \delta)(k\mu + \lambda)^{s} - \delta (k\mu)^{s}]}{(3\lambda + \alpha + \delta)(k\mu)^{s}}. \]
3. Comparison of the three availability systems

Click here and insert your conclusions text. We consider \( \lambda = 0.001, \alpha = 0.0005, \mu = 0.1, \delta = 2.4 \).

Comparison for the \( Av_i \)

We first consider the following three cases:

Case 1. We fix \( \alpha = \lambda / 2, \mu = 0.1, \delta = 2.4 \), and vary the values of \( \lambda \) from 0.001 to 0.02.

Case 2. We fix \( \lambda = 0.001, \alpha = \lambda / 2, \delta = 2.4 \), and vary the values of \( \mu \) from 0.04 to 0.16.

Case 3. We fix \( \lambda = 0.001, \alpha = \lambda / 2, \mu = 0.1 \), and vary the values of \( \delta \) from 1 to 10.

From Tables 1–3, numerical results can be found in analyzing the values of the \( Av_{ir}, Av_{ie}, Av_{id} \) (i = 1, 2, 3). We first note that the rank of three availability systems sorted by their steady-state availability does not depend on distributions of repair time but on the values of \( \lambda, \mu \), and \( \delta \). Next, we note that the steady-state availability of system 1 is larger than systems 2 and 3 for all cases.

Table 1. Comparison of the availability systems 1, 2, 3 for \( Av_i( \lambda = \alpha = \lambda / 2, \mu = 0.1, \delta = 2.4 \) )

3. Repair times. Next, for each availability system, the explicit expressions for the \( Av \) for three different repair time distributions, such as exponential, 3-stage Erlang, and deterministic are developed. Finally, we rank three availability systems based on the \( Av_i \) for three various repair time distributions.

4. Conclusions

In this paper, we first derive the steady-state availability \( Av \) of three availability systems with warm standby components, fault detection delay and general repair times. Next, for each availability system, the explicit expressions for the \( Av \) for three different repair time distributions, such as exponential, 3-stage Erlang, and deterministic are developed. Finally, we rank three availability systems based on the \( Av_i \) for three various repair time distributions.
